## ABSTRACT

---

# Estimating Causal Effects of Alcohol Access and Use on a Broad Set of Risky Behaviors: Regression Discontinuity Evidence\*

A growing body of evidence suggests large increases in criminal behavior and mortality coinciding with a young adult's 21st birthday, when alcohol consumption becomes legal. The policy implications from these findings have focused on the need to reduce drinking among young people, potentially by enforcing stricter alcohol controls. However, mortality and arrests are relatively infrequent outcomes and relatively less is known about the intermediate and more prevalent consequences of legal access to alcohol at age 21. This paper uses the Add Health data combined with a regression discontinuity approach to examine the effects of alcohol access on sexual behavior, drunk driving, violence, and other outcomes. The results suggest relatively large effects that appear concentrated in men. The sample also allows some suggestive policy implications on whether changing the minimum drinking age may reduce these consequences.

\* The author thanks Kitt Carpenter, Carlos Dobkin, Michael Grossman, and Bob Kaestner for very helpful comments. This research uses data from Add Health, a program project directed by Kathleen Mullan Harris and designed by J. Richard Udry, Peter S. Bearman, and Kathleen Mullan Harris at the University of North Carolina at Chapel Hill, and funded by grant P01-HD31921 from the Eunice Kennedy Shriver National Institute of Child Health and Human Development, with cooperative funding from 23 other federal agencies and foundations. Special acknowledgment is due Ronald R. Rindfuss and Barbara Entwisle for assistance in the original design. Information on how to obtain the Add Health data files is available on the Add Health website (<http://www.cpc.unc.edu/addhealth>). No direct support was received from grant P01-HD31921 for this analysis.

## **Introduction**

While there are well documented effects of alcohol access and heavy drinking on mortality and arrests, less causal evidence is available for a host of other, highly prevalent alcohol-related behaviors, such as risky sexual activity, violence, drunk driving, and potentially complementary substance use<sup>1</sup>, among others. Despite decades of policy interventions to curb problem drinking among adolescents and young adults as well as a large volume of research attempting to estimate the effects of problem drinking on a host of outcomes, little convincing evidence is available.

One of the most visible policies the US employs to curb problem drinking is the use of a Minimum Legal Drinking Age (MLDA) law that for over the past two decades has criminalized alcohol use below the age of 21 in the US<sup>2</sup>. There is a large literature that uses state variation in these laws from the 1980s to show negative effects on alcohol consumption and traffic accidents (see Wagenaar and Toomey 2002 for review). More recently, researchers have used the strict age cutoff generated by the law to show strong evidence of increases in problem drinking, alcohol related mortality, and criminal behaviors following individuals' 21<sup>st</sup> birthdays (e.g. Carpenter and Dobkin, 2009, 2015 Carpenter and Dobkin 2011 for a review). However, while there is clear evidence on this limited set of relatively infrequent outcomes, less is understood about the effects of alcohol use and misuse on a broader set of intermediate and more highly prevalent outcomes, such as drunk driving<sup>3</sup>, risky sexual behaviors, violent acts, and drug use.

---

<sup>1</sup> Crost and Guerrero (2012) find that the MLDA reduces marijuana use. Yoruk and Yoruk (2011) find no effects on tobacco use of the MLDA. Deza (2015) finds evidence for hard drug use. York and Yoruk (2015) finds limited evidence for birth control use and sexual activity.

<sup>2</sup> The MLDA was created through the Federal Uniform Drinking Age Act (FUDAA), signed by Ronald Reagan on July 17, 1984, which threatened to withhold highway construction funds from states that failed to increase their minimum legal drinking age to 21 by October 1, 1986 (Miron and Tetelbaum 2009).

<sup>3</sup> Carpenter and Dobkin (2015) examine *arrests* for drunk driving but are unable to examine the overall increase in drunk driving with only arrest data.

The current focus in the literature on examining the impacts of alcohol access on mortality, arrests, and some measures of drug use is problematic both in limiting understanding of the comprehensive impacts of the MLDA on behaviors that may be complements or substitutes with alcohol use and also in limiting our understanding of potentially important determinants of many risky behaviors (e.g. dating violence) that are speculated to be related to alcohol use, but have not been the subject of causal investigations. This paper expands on the use of the strict MLDA age-cutoff to further examine impacts of the law and extending analysis to previously unexplored or underexplored risky behavior outcomes.

In addition, the current MLDA policy has come under increased scrutiny and re-evaluation. Several states have recently considered proposals to reduce their drinking age, including South Dakota, Vermont, and Missouri (Lovenheim and Slemrod 2010). There has also been a widely publicized proposal by over 100 university and college presidents to reduce the MLDA to 18 because of the negative consequences of prohibition to age 21 (see Amethyst Initiative 2008). Lowering the age to 18 would allow individuals to be initially given legal access to alcohol while most are still living with their parents, who might more successfully oversee this transition and may blunt the associated increase in binge drinking and related consequences. This paper presents some exploratory analysis that may provide some suggestive evidence related to this current policy question.

Specifically, this paper uses the variation generated by the increase in legal alcohol access at age 21 in the US to replicate prior examinations on the impacts on binge drinking, drug use, and some measures of criminal activity, and extends the literature by exploring several novel measures of risky behaviors, including self reports of (rather than arrests for) drunk driving, drinking-related risky sex, interpersonal troubles, hangovers, and violence. Results suggest that,

on average, access increases binge drinking but has few other consequences. However, the effects vary considerably by gender, where females (but not males) are more likely to initiate alcohol use at age 21, males substantially increase binge drinking at age 21. In addition, males (but not females) face an increased risk of problems with friends and risky sexual activity at age 21. There is also some evidence of an increase in drunk driving and violence. Finally, in order to provide suggestive evidence of one dimension of the policy consideration of lowering the MLDA, I also stratify the results based on the living arrangement of the young adults. The findings suggest no harm reduction associated with binge drinking for those individuals living with their parents around age 21; in fact, individuals living with their parents (regardless of whether they are in school) have larger increases in alcohol related risky behaviors than individuals living away from their parents.

## **Literature Review**

Alcohol use and misuse are among the most common causes of mortality and morbidity in the US and around the world. Alcohol misuse not only harms many of the body's organ systems and facilitates various medical problems, including cardiovascular disease and liver cirrhosis, but it contributes to injuries, automobile collisions, and violence (U.S. DHSS 2000). Short and long-term consequences of early alcohol use include increases in risky behaviors, negative health, and estimated costs to the U.S. of \$53 billion annually. Despite ongoing policy interventions, over 25% of 12-20 year olds drink alcohol, and nearly 25% of those in high school frequently binge drink<sup>4</sup>.

One of the primary policies to combat alcohol misuse is to shift consumption to older ages, in part through the Minimum Legal Drinking Age (MLDA) of 21 in the US. A large

---

<sup>4</sup> <http://www.cdc.gov/alcohol/fact-sheets/underage-drinking.htm>

volume of research has shown evidence that the MLDA is inversely related to alcohol consumption and traffic accidents (see Wagenaar and Toomey 2002 for a review up to 2000).<sup>5</sup> However, much of this previous research relies on relatively weak empirical methods to produce causal evidence. As discussed by Carpenter and Dobkin (2009), the previous literature typically uses variation from the early 1980's based on a small number of states who changed their MLDA before complying with the federal age of 21. Since the set of states that decreased their legal drinking ages and the speed at which these states complied with the federal legal age are likely non-random, alternative strategies to estimate the causal effect of consumption on health outcomes are needed<sup>6</sup>. Additionally, although most studies show negative effects of the MLDA on drinking, the range of estimates is also somewhat wide. For example, Cooke and Moore (2001) find a 17 percent reduction in binge drinking, Dee (1999) finds an 8 percent reduction, and Carpenter et al. (2007) find a 4 percent reduction. Using a national representative dataset of a new cohort of adolescents and young adults can add to the array of point estimates in the literature.

Several researchers have used a regression discontinuity design to circumvent issues with previous research, where individuals who are close to their 21<sup>st</sup> birthday are compared along multiple outcomes, including alcohol use, heavy alcohol use, and alcohol-related outcomes including mortality and criminal behavior. That is, MLDA produces sharp differences in alcohol access for young adults on either side of age 21. Since the observed and unobserved determinants of alcohol consumption and other outcomes are likely to trend smoothly across the age-21

---

<sup>5</sup> A larger literature has examined the impacts of other policies on youth binge drinking, (e.g. the minimum wage by Hoke and Cotti 2015).

<sup>6</sup> See Miron and Tetelbaum (2009), who present evidence that any MLDA impact on reductions in traffic fatalities was driven by states who increased their age requirement before being induced by the federal government, suggesting endogeneity of the timing of policy adoption. See also Kaestner (2000), who finds mixed evidence on the effects on MLDA on alcohol consumption.

threshold, we can assume that discontinuous jumps in alcohol consumption and risky behaviors associated with alcohol that occur at age 21 can identify the causal effect of consumption on these behaviors among young adults.

Specifically, Carpenter and Dobkin (2008) use repeated cross sectional data from the California Health Interview Survey (CHIS) for 2001, 2003, and 2005 to show a 16 percentage point increase in alcohol use in the past month and an 8 percentage point increase in binge drinking in the past month for those who recently turned 21 years old. They go on to document a 6 percent increase in overall arrests at age 21, largely made up of violent crimes (e.g. assaults) and alcohol-related arrests (e.g. DUI, drunkenness). See Carpenter and Dobkin (2011, 2015) for a review of this literature and their results and Hansen and Waddell (in press) for recent evidence on larger effects for those with prior criminal arrests.

More recently, several papers have examined the potential spillover impacts of legal alcohol access on other substance use<sup>7</sup>. Yoruk and Yoruk (2011) find some evidence that the MLDA increases marijuana use, suggesting complements, and no effect on tobacco consumption. However, Crost and Rees (2013) dispute the finding for marijuana and show it is due to a sample restriction by Yoruk and Yoruk. Crost and Guerrero (2012) show evidence that alcohol and marijuana may be substitutes, using the same RD design as the previous studies but a new dataset. Deza (2015) finds reductions in the use of hard drugs.

Besides the evidence of large criminal behavior and mortality effects and the mixed evidence on other substance use in the recent literature, little is known about other consequences of alcohol consumption using a convincing research design. That is, alcohol consumption, especially binge drinking, likely produces a host of other impacts on other risky behaviors

---

<sup>7</sup> A larger literature assesses the evidence of whether alcohol are other unhealthy consumer goods (i.e. tobacco) are substitutes or complements (e.g. Tauchmann et al. 2013)

(sexual behaviors, violence and drunk driving (in addition to the arrests), and problems with social relationships). Understanding the effects on these additional and more prevalent behaviors can complement the known effects on less prevalent outcomes, such as mortality and arrests.

Thus this paper introduces a new dataset to the literature on MLDA laws by using national survey data from the Add Health to produce graphical and regression based evidence that MLDA laws produce sharp differences in alcohol consumption and a variety of risky behaviors related to alcohol use for youths on either side of the age-21 cutoff. The evidence suggests that the MLDA reduces binge drinking by approximately 5 percentage points as well as a variety of other consumption measures. The results also show that for males, there are marked increases in reports of drunk driving, risky sexual activities, violence, and interpersonal problems with friends. In contrast, and conflicting with some recent evidence in the literature, no evidence is found on relationships with tobacco, or marijuana. The results are then stratified by living arrangements to provide suggestive evidence of whether changing the MLDA may reduce harm.

### **Data and Empirical Results**

This paper uses data from the Add Health in order to examine the discontinuities in alcohol consumption and related risky behaviors around the individual's 21<sup>st</sup> birthday. Add Health is a school-based, longitudinal study of the health-related behaviors of adolescents and their outcomes in young adulthood. Beginning with an in-school questionnaire administered to a nationally representative sample of students in grades 7 through 12 in 1994-95, the study follows up with a series of in-home interviews of students approximately one year and then six years later. Other sources of data include questionnaires for parents, siblings, fellow students, and school administrators. By design, the Add Health survey included a sample stratified by region,

urbanicity, school type, ethnic mix, and size. Preexisting databases (e.g. census data) have been linked with the individuals in the sample and provide information about neighborhoods and communities.<sup>8</sup>

Fortunately, the third wave of data collection occurred when the individuals in the original sample were between 18-26 years old, with an average age of 22. Data is available for the month/year of birth, which is matched to information indicating the day, month, and year of the Wave 3 interview. Following Carpenter and Dobkin (2008), who use the repeated cross-sectional data available in the California Health Interview Survey, I restrict the age range to be between 19-22 years old at the time of interview. Because the focus of the Add Health data was on risky health-related behaviors of adolescents and young adults, this dataset will allow a rich set of drinking related outcomes not available in other surveys.

In particular, this paper focuses on drinking outcomes, such as any alcohol use, binge use, and frequency of use as well as drinking related risky behaviors, such as being drunk at work, drunk driving, having problems with friends, dates, and others while drinking, being hung over, and other outcomes. In order to also examine the potential heterogeneity of effects, I stratify the analyses by gender. Finally, in order to provide some suggestive evidence on the efficacy of changes to the current minimum drinking age, I stratify the analysis based on the current living arrangement and school attendance status of the respondents.

Table 1 represents summary statistics of the available data for the sample of individuals ages 19-22 at the time of interview (summary statistics for the full sample are presented in Table

---

<sup>8</sup> See for further information: <http://www.cpc.unc.edu/projects/addhealth>

1A in the appendix). Table 2 stratifies the summary statistics by gender. The appendix outlines the definitions of the variables used in the analyses.<sup>9</sup>

In order to provide evidence consistent with the use of the RD approach, I show that the density of individuals in the sample is smooth through the Age 21 cutoff and that the characteristics of the individuals (e.g. race, gender, maternal education and family income) are also smooth. Table 3 provides the results of these examinations. Figure 1 plots the data by age in months centered at 252 months (Age 21). Neither result suggests a discontinuity in the density of individuals in the data. Next, the remaining columns of Table 3 present the empirical tests of smoothness in exogenous characteristics; the only result that is statistically significant is for “other race”, which is only significant in the linear specification. See Figure 2 for graphical evidence of smoothness of the exogenous characteristics. These results and those that follow are produced using a simple linear specification for the running variable (age-in-months):

$$y = \beta_0 + \beta_1(\text{age}) + \beta_2 I(\text{age} \geq 21) + \varepsilon$$

The purpose of the analysis in this paper is to leverage findings from previous literature that have shown that the causal effect estimates typically do not change very much in the RD literature using MLDA based on using quadratic, cubic, quartic polynomials in age, when interacting age with the threshold, or when adding control variables. Since this paper examines over 20 outcomes, the focus on the linear specification is mainly to conserve space and limit the number of tables. However, results do not change if instead a quadratic in age is used nor whether interactions are estimated between the running variable and the threshold measure or whether additional control variables are used (see selected results in Appendix Table 3A). The latter is

---

<sup>9</sup> There may be a concern with various reporting biases of alcohol activities. However, the Add Health survey uses headphones and computer assisted personal interviewing (CAPI) software so that the respondents are not directly reporting to the interviewer, but rather inputting any potentially embarrassing, illegal, or non-normative behaviors directly into a laptop.

not surprising given the balance of control variables through the discontinuity (see Table 3). The standard errors are clustered on the running variable, following Lee and Card (2008).

## **Results**

The first set of results examines the “first stage” relationship—the effect of an increase in alcohol access on alcohol consumption. As seen in Table 4, overall the results mimic those in Carpenter and Dobkin (2008, 2009) closely. I find a small and statistically insignificant increase in alcohol participation and a statistically significant increase in any binge drinking in the previous year (4.6 percentage points compared to approximately 5 percentage points reported in Carpenter and Dobkin 2009) as well as an increase in the number of days drinking in the previous year (7.2 days or approximately a 17% increase, compared with a 21% increase in Carpenter and Dobkin 2009). See Figure 3 for graphical evidence.

Unlike the NHIS data, which only has yearly measures of binge drinking status, the Add Health has a measure of binge drinking over the previous two weeks. This measure shows an increase of 5.1 percentage points off a base of 32%; Carpenter and Dobkin (2008) show an 8.9 percentage point increase in binge drinking over the past month using the CHIS data. See Figure 4 for graphical evidence of the binge drinking result<sup>10</sup>. This result also suggests that much of the increase in binge drinking in the previous year is from recent binge drinking, which further reinforces the importance of the increase in alcohol access at age 21. The persistence in elevated binge drinking over 10 months past turning 21 suggests that the effect is more than just a temporary “celebration effect”.

---

<sup>10</sup> There may also be a concern that the estimates are picking up more general “birthday effects”. Following Carpenter and Dobkin 2015 and Carrell et al. 2011, I show in the appendix that there are no effects if an Age-20 cutoff is used instead. The reader can also visually examine the Figures in order to examine the effects during the birthday month versus later months.

To further examine the effects of alcohol access, Table 4G stratifies the results by gender and shows that, while the gender differences are not statistically significant, the magnitudes are relatively large in some cases. Here, the results suggest an increase in ever-drinking for females of nearly 4 points but no effect for males (Carpenter and Dobkin 2009 do not find any evidence of increases in alcohol participation). While the effects of turning 21 on previous year binge drinking and drinking days is similar by gender, the effects of binge drinking the previous two weeks is over twice as large for men (8 points) than women (less than 4 points), as is the effect on the number of binge days in the previous two weeks. See Figure 5 for graphical evidence.

While the mortality and criminal consequences of alcohol access at age 21 have been shown by Carpenter and Dobkin (2009, 2015), much less is known about the potential for increases in more prevalent risky behaviors associated with alcohol misuse that fall short of these “catastrophic” outcomes. Table 5 presents these estimates for a wide range of risky behaviors associated with heavy drinking, including (self reported) drinking and driving, work problems, relationship problems, risky sex and fighting due to drinking. Although all the coefficients suggest 1-2 point increases in these outcomes, only the effect on having “any problems with friends due to drinking” is statistically significant for the full sample.

As in the last set of results, I stratify the analysis by gender in Table 5G to further examine these problem behaviors. The results suggest some relatively large and statistically significant effects of turning 21 on several risky behaviors for men but no effects for women. In particular, there is a nearly 4 point increase in reporting drinking and driving in the past five years (mean level of 29%), there is also a 6 point increase in having sex due to alcohol use that the respondent later regretted (mean level of 18%)<sup>11</sup>. See Figure 6 and 7 for graphical evidence.

---

<sup>11</sup> Carpenter (2005) uses state variation in Zero Tolerance Laws to show evidence that alcohol use increases gonorrhea rates for males. Fertig and Watson (2009) show that the MLDA likely reduces unplanned pregnancies.

In addition to examining a range of consequences directly related to alcohol consumption, Table 6 outlines relationships with other, potentially related health behaviors. Overall, there is no detectable evidence of increases in suicidal thoughts or attempts as well as no evidence that tobacco or marijuana use change discontinuously at age 21, which is suggestive evidence against strong complementarities with these substances and alcohol use<sup>12</sup>. Although not reported, there were also no detectable differences by gender for the outcomes in Table 6.

### *Potential Policy Implications*

Overall, the findings have suggested some relatively large effects of the minimum drinking age law on heavy alcohol use and associated risky behaviors, such as drunk driving and risky sexual activity, which have been shown to be concentrated among men. These results have complemented the work by Carpenter and Dobkin (2009, 2015), who show large effects on mortality and criminal behavior of access to alcohol after turning 21. The estimates also echo some new evidence from Yoruk and Yoruk (2011) that alcohol is not strongly complementary with marijuana or tobacco in this, alternative, sample.

An important policy question related to these findings is whether we might change the legal age, either by moving it back to age 18 or even moving later, past college-age. For example, as discussed above, over 100 university and college presidents have recently suggested benefits from replacing the current age 21 laws with age 18 laws because of the development of a “culture of binge drinking” on college campuses. An implication is that individuals who are

---

<sup>12</sup> In contrast, Dee (1999) finds that MLDA reduced teen smoking participation by 3 to 5% and also shows evidence that higher cigarette taxes are associated with lower teen drinking, though the latter results are imprecise. Yoruk and Yoruk (2011) also find no impacts on tobacco use. As discussed above, the impacts on marijuana use have been mixed in the literature.

given access to alcohol in other contexts, such as at age 18 when they are living with their parents, might face fewer drinking-related problems.

While it is exceedingly difficult to apply the results from this and other studies to this policy question, there may be some suggestive evidence allowed by the use of the rich dataset that contains information on the living context of the respondents. This section presents evidence of whether individuals who live with their parents at age 21 respond differently to legal access to alcohol than individuals who do not live with their parents. I also examine differences based on whether the respondent is currently in college. Table 7 shows virtually no evidence of differential effects on problem drinking at age 21 based on living context. Indeed, there is suggestive evidence of a greater number of binge days for respondents living with their parents (regardless of schooling). In Table 8, I further examine this issue by estimating the effects of alcohol access on alcohol related risky behaviors and outcomes. Again, though few results are statistically different between individuals in alternative living arrangements, the evidence suggests *larger* negative effects for those living with their parents. This analysis is meant to be suggestive; it could be the case that living arrangements are endogenously determined based on considerations about legal access to alcohol, but with little evidence for lowering the minimum legal drinking age, it may be premature to experiment with such a policy<sup>13</sup>.

## **Conclusion**

This paper provides new causal estimates of the effects of alcohol availability associated with turning 21 years old on a host of alcohol related behaviors, such as heavy drinking, drunk driving, and other inter-personal problems. The RD design provides a relatively straightforward

---

<sup>13</sup> See Lovenheim and Slemrod (2010) for evidence that reductions in MLDA could increase traffic fatalities from individuals who drive to the jurisdiction to take advantage of the law.

estimation procedure and graphical representation of the effects of access on risky behaviors. This design also has the advantage of allowing tests of the identifying assumptions, suggesting little evidence of several biases.

The paper provides new evidence of several research questions. First, like Carpenter and Dobkin (2009) and others, the results suggest that initiation into alcohol use at age 21 does not seem to be responsible for the patterns of risky behaviors. Second, while the consequences of MLDA for mortality and criminal activities are known, little evidence has been produced on more highly prevalent and intermediate effects of alcohol consumption. The results in this paper show these intermediate effects are non-trivial and concentrated among men.

A natural policy question is what to do about these consequences of the law—should we change the MLDA to age 18 or 25 or some other age? One principal recent argument for reducing the MLDA is to change the context of first legal alcohol access from the college dorm to the family environment by moving the age back to 18. The results in this paper provide no evidence consistent with this argument and suggest that individuals living with their parents face even higher consequences of legal alcohol access than individuals living away from their parents. There may be other compensating benefits of moving the MLDA back to 18, but these initial results do not lend optimism to the efficacy of a reduction in the MLDA. However, more definitive research needs to be done on this important policy question.

Table 1A:  
Descriptive Statistics for Analysis Sample and Full Sample (N~15,000 and 8,700)

Variable	Mean	Std Dev	Mean	Std Dev
	Full		Analysis	
Ever Drink	0.74	0.44	0.82	0.38
Days Drink in Last 12 Month (Categories)	44.27	68.18	44.27	67.78
Driven while drunk in past 5 years	0.23	0.42	0.22	0.41
Any Binge in Past Year	0.47	0.50	0.47	0.50
Days Binge in Last 12 Months (Categories)	20.32	49.02	21.05	49.12
Any Binge in Past 2 Weeks	0.32	0.47	0.32	0.47
Times Binge in Last 2 Weeks	0.90	1.92	0.95	1.97
Drunk at school/work in past year	0.05	0.22	0.06	0.23
Problems at Work/School in Past 12 Months from Drinking	0.10	0.47	0.11	0.50
Any Problems with Friends in Past 12 Months from Drinking	0.08	0.27	0.08	0.28
Problems with Friends in Past 12 Months from Drinking	0.12	0.48	0.13	0.49
Problems with Date in Past 12 Months from Drinking	0.16	0.58	0.17	0.58
Any Problems with Date in Past 12 Months from Drinking	0.10	0.30	0.10	0.30
Times Hungover in Past Year	0.92	1.32	0.94	1.33
Any Hungover in Past Year	0.41	0.49	0.41	0.49
Regretted Sexual Situation in Past Year Because Drinking	0.22	0.64	0.24	0.65
Any Regretted Sexual Situation in Past Year Because Drinking	0.14	0.35	0.15	0.36
Fight because drinking in past year	0.12	0.49	0.13	0.51
Any Fight because drinking in past year	0.07	0.26	0.08	0.27
Any Suicidal Thoughts in past year	0.06	0.24	0.07	0.25
Any Suicidal Attempts in past year	0.02	0.12	0.02	0.14
Ever Arrested	0.11	0.31	0.11	0.32
Smoke Marijuana	0.21	0.41	0.23	0.42
Frequency of Marijuana Use	3.51	16.33	3.80	16.52
Smoke Tobacco	0.32	0.47	0.33	0.47
Frequency of Tobacco Use	3.62	7.73	3.66	7.60
Male	0.49	0.50	0.46	0.50
Black	0.23	0.42	0.23	0.42
Hispanic	0.17	0.38	0.14	0.35
Other Race	0.08	0.27	0.07	0.25
Running Variable (Month from Age 21)	3.50	13.20	3.50	13.20
Age	21.96	1.77	20.77	1.08
Age 21 or greater	0.77	0.42	0.62	0.49
Alcohol Available during High School	0.29	0.45	0.29	0.45
In School	0.37	0.48	0.46	0.50
Live with parent	0.41	0.49	0.46	0.50
Live with parent/in school	0.17	0.37	0.21	0.41
Do not live with parent/in school	0.21	0.41	0.25	0.43

Notes: Full sample include all individuals in the Add Health (age 18-26); Analysis sample includes individuals ages 19-22 at Wave 3.

Table 2A  
 Birthday Effects: Age-21 versus Age-20

Outcome	Ever Drink	Drink Days (year)	Any Binge Year	Binge Days Year	Any Binge 2 weeks	Binge Days 2 Weeks
Age >= 21	0.020 (0.018)	7.209*** (2.618)	0.046*** (0.017)	2.305 (1.935)	0.051** (0.019)	0.175** (0.087)
Recentered Age in Months	0.002*** (0.001)	0.052 (0.104)	-0.001 (0.001)	-0.063 (0.072)	-0.001* (0.001)	-0.006* (0.003)
Observations	8764	8720	8673	8727	8706	8706
R-squared	0.009	0.004	0.001	0.000	0.001	0.000

Outcome	Ever Drink	Drink Days (year)	Any Binge Year	Binge Days Year	Any Binge 2 weeks	Binge Days 2 Weeks
Age >= 20	0.011 (0.020)	-0.997 (2.499)	-0.021 (0.022)	0.021 (1.838)	0.017 (0.021)	0.143 (0.087)
Recentered Age in Months	0.003*** (0.001)	0.313*** (0.078)	0.001 (0.001)	0.016 (0.053)	-0.000 (0.001)	-0.003 (0.002)
Observations	8909	8864	8818	8872	8851	8851
R-squared	0.009	0.004	0.000	0.000	0.000	0.000

Notes: This table reports RD effects comparing an Age 21 cut-off (Top Panel) to an Age 20 cut-off (Bottom Panel) to explore potential birth day effects at Age 21 that might confound the results. Standard errors clustered on running variable.

Table 3A  
 Robustness Checks of Main Results: Quadratic and Interaction Specifications

Notes: This Table extends prior Tables (e.g. Table 4) by using the same outcome and comparing the results from linear specification (Baseline) to results using quadratic specifications (Quad), specifications that interact the running variable with the treatment (Inter) and specifications using a quadratic specification with interactions of both the running variable and the running variable-squared (Quad/Inter). RV-squared: Running Variable X Running Variable, Running X: Interaction between the running variable and the age-21 threshold. The coefficient for the running variable-squared X age>21 are not shown.

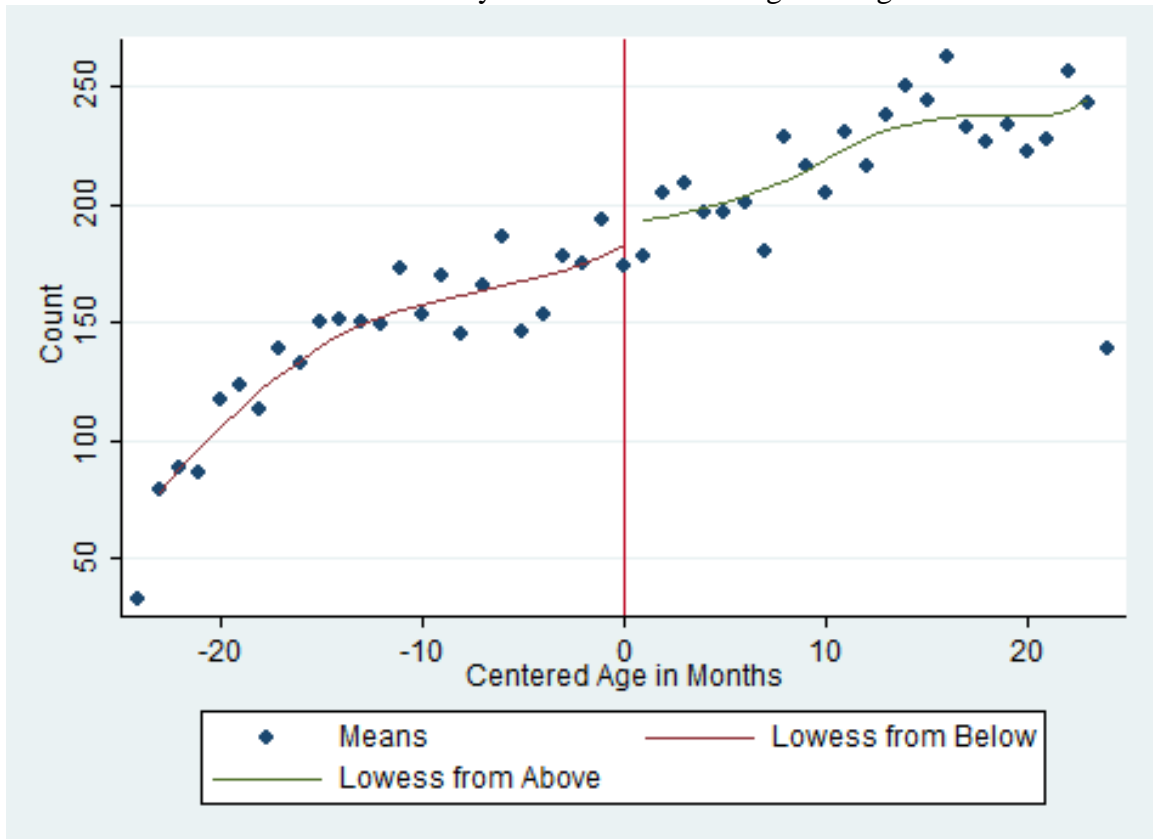

## Appendix: Variable Definitions

Variable	Survey Question
Ever Drink	Whether reported ever drinking at wave 1, 2 or since wave 2
Days Drink in Last 12 Month (Categories)	During the past 12 months, on how many days did you drink alcohol? 1 or 2 days in the past 12 months (=1); 3 to 12 times in the past 12 months (=10); 2 or 3 days a month (=25); 1 or 2 days a week (=50); 3 to 5 days a week (=150); every day or almost every day (=300)
Driven while drunk in past 5 years	Since June 1995, have you driven while drunk?
Days Binge in Last 12 Months (Categories)	During the past 12 months, on how many days did you drink five or more drinks in a row? 1 or 2 days in the past 12 months (=1); 3 to 12 times in the past 12 months (=10); 2 or 3 days a month (=25); 1 or 2 days a week (=50); 3 to 5 days a week (=150); every day or almost every day (=300)
Times Binge in Last 2 Weeks	During the past two weeks, how many times did you have five or more drinks on a single occasion, for example, in the same evening?
Any Binge in Past 2 Weeks	if Times Binge >0
Problems at Work/School in Past 12 Months from Drinking	During the past 12 months, how many times did you: You had problems at school or work because you had been drinking
Problems with Friends in Past 12 Months from Drinking	You had problems with your friends because you had been drinking
Any Problems with Friends in Past 12 Months from Drinking	
Problems with Date in Past 12 Months from Drinking	You had problems with someone you were dating because you had been drinking.
Any Problems with Date in Past 12 Months from Drinking	
Times Hungover in Past Year	Over the past 12 months, how many times: Were you hung over?
Any Hungover in Past Year	
Regretted Sexual Situation in Past Year Because Drinking	did you get into a sexual situation that you later regretted because you had been drinking?
Any Regretted Sexual Situation in Past Year Because Drinking	
Fight because drinking in past year	did you get into a physical fight because you had been drinking
Any Fight because drinking in past year	
Drunk at school/work in past year	were you drunk at school or work?
Any Suicidal Thoughts in past year	
Any Suicidal Attempts in past year	
Own a Handgun	
Alcohol Available during High School	Is alcohol easily available to you in your home? (asked at Wave 1)
In School	Are you going to school full time or part time?
Live with parent	Where do you live now? A: Your Parents' home
Live with parent/in school	Both live with parents and in school
Do not live with parent/in school	Do not live with parents and in school

Figures

Figure 1  
Evidence of Smooth Density of Individuals Through the Age 21 Cutoff

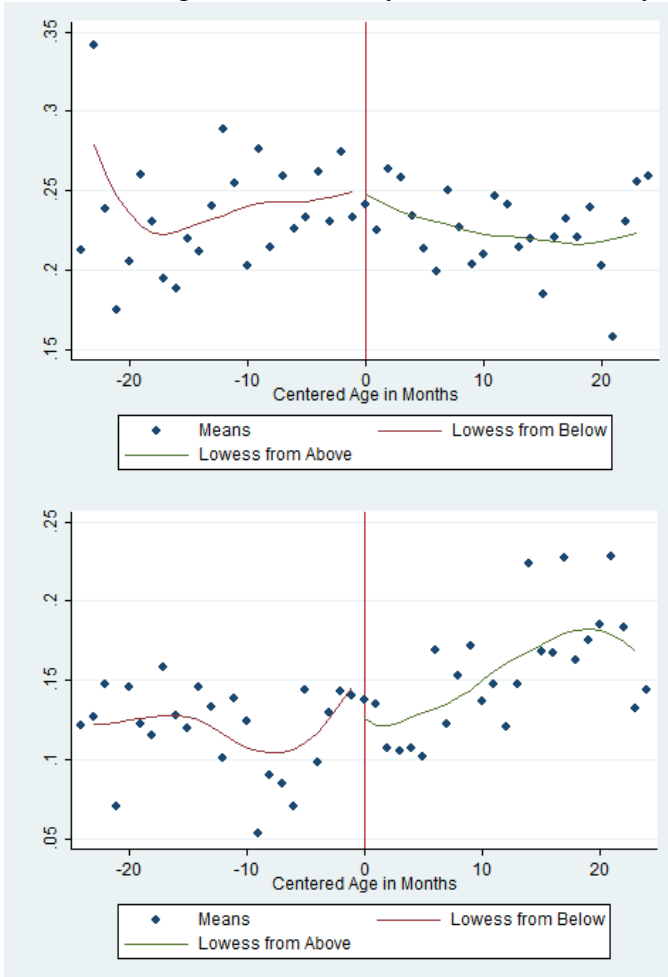

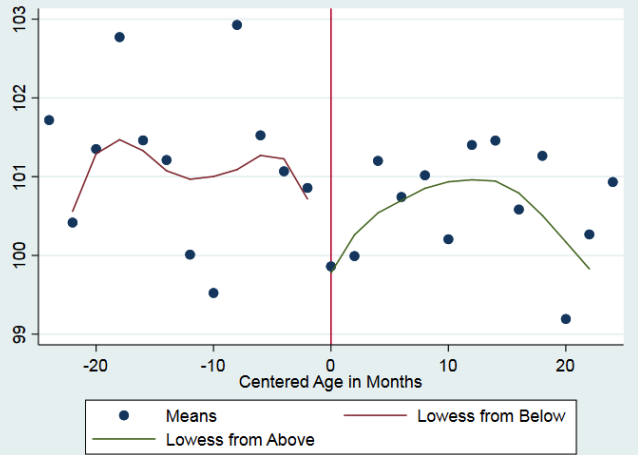

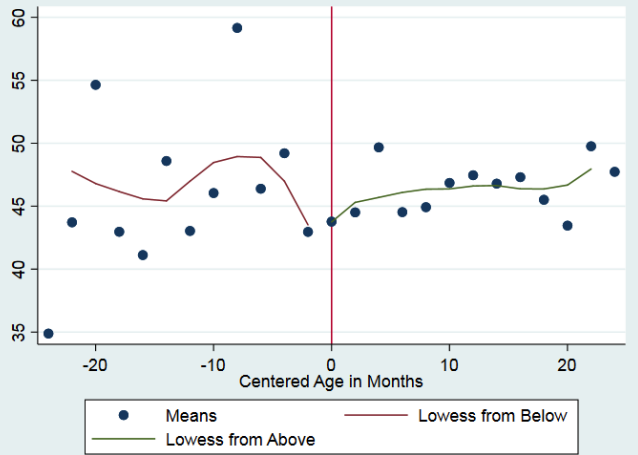

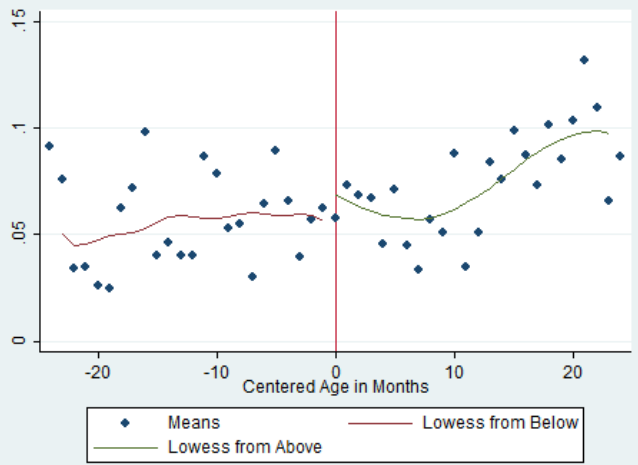

Notes: The figure shows the counts of individuals in the data by age-month at time of interview, centered at age-month 252 (Age=21) and includes individuals between 19 and 23 years old. A lowess smoother is plotted over the points. This note applies to future figures.

Figure 2

Evidence of Smoothness of Exogenous Variables

Figure (A) Black; Figure (B) Hispanic; Figure (C) Other Race; Figure (D) Family Income at Wave 1; Figure (E) Peabody Picture Vocabulary Test at Wave 1

Figures for Alcohol Behaviors
